# CMPS 312

Model-View-ViewModel (MVVM) Architecture

Dr. Abdelkarim Erradi

CSE@QU

Outline

1. Model-View-ViewModel (MVVM)

2. ViewModel

3. Mutable State

4. LiveData

5. Flow

MVVM Architecture

Model-View-ViewModel (MVVM) Architecture

**View** = UI to get input from the user.

- It observes data changes from the ViewModel to update the UI accordingly

- Calls the ViewModel to handle events such as button clicks, form input, etc.

ViewModel

➢ Manages **state** (i.e, data needed by the UI)

  • Interacts with the Model to read/write data based on user input

  • Expose the state as **Observables** that the UI can subscribe-to to get data changes

➢ Implements UI logic / computation (e.g., data validation)

Model - handles data operations

➢ Model has entities that represent app data

➢ Repositories read/write data from either a Local Database (using **Room** library) or a Remote Web API (using **Retrofit** library)

➢ Implements data-related logic / computation
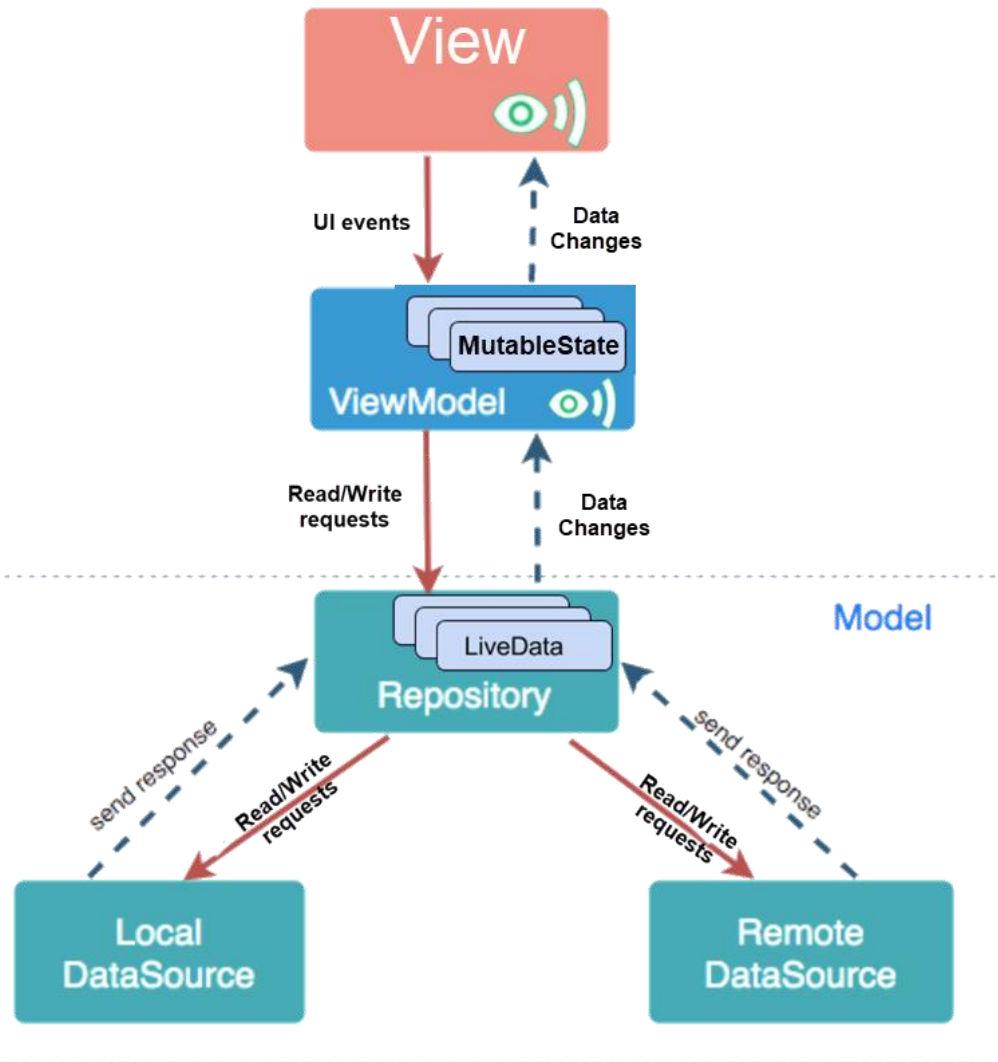

MVVM Key Principles

- <u>Separation of concerns</u>:
  - View, ViewModel, and Model are **separate components** with distinct roles

- <u>Loose coupling</u>:
  - ViewModel **has no direct reference to the View**
  - View never accesses the model directly
  - Model unaware of the view

- <u>Observer pattern</u>:
  - View observes the ViewModel (to get data changes)
  - ViewModel observes the Model (to get data changes)

- <u>Inversion of Control</u>:
  - Uses <u>Dependency Injection</u> instead of direct instantiation of objects

  *e.g., val scoreViewModel = **viewModel**<ScoreViewModel>()*
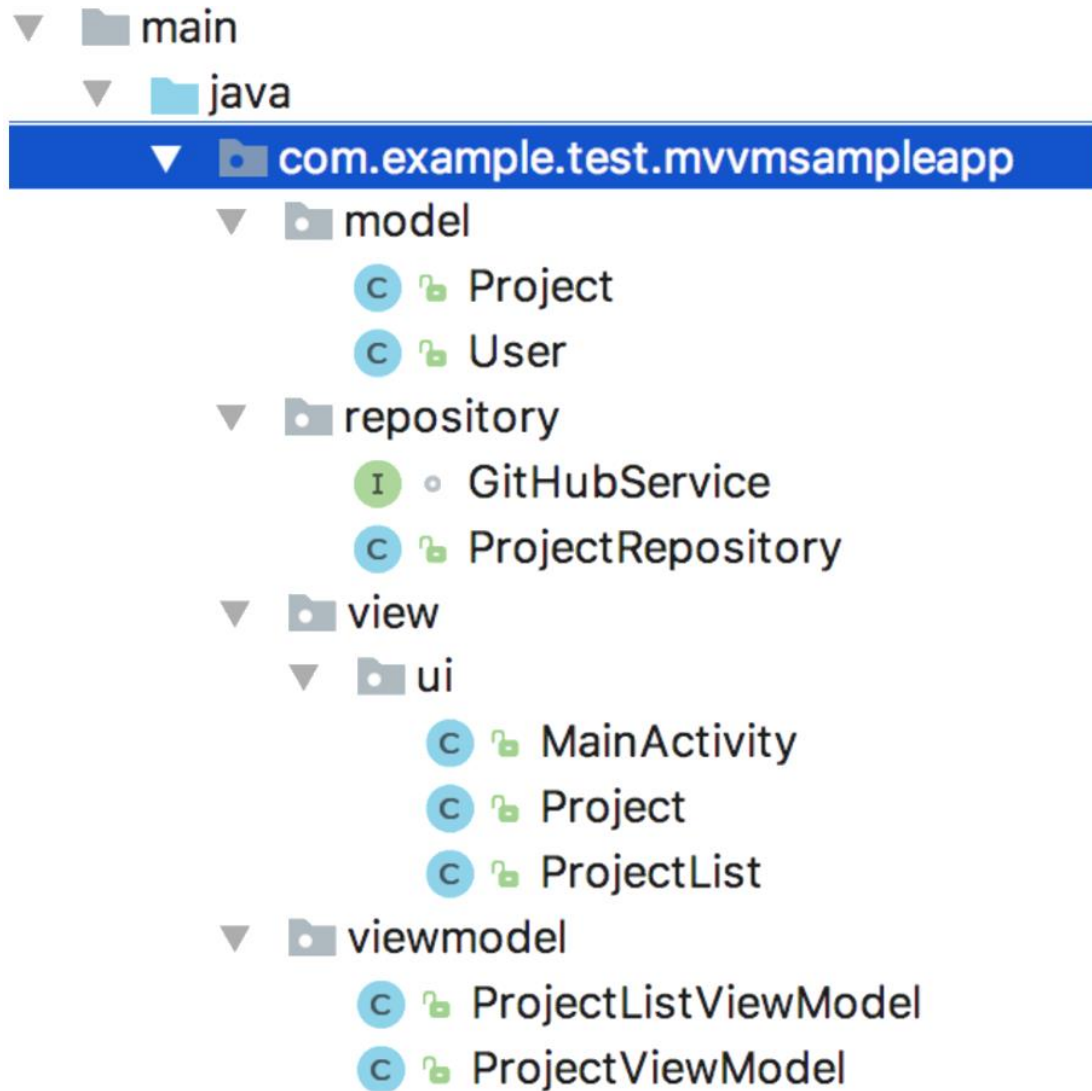

Advantages of MVVM

- ***Separation of concerns =*** **separate UI from app logic**

  - App logic is not intermixed with the UI. Consequently, code is cleaner, flexible and easier to understand and change

  - Allow changing a component without significantly disturbing the others (e.g., View can be completely changed without touching the model)

  - Easier **testing** of the App components

MVVM => Easily maintainable and testable app
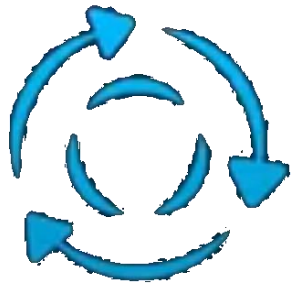

Android Architecture Components

- Android architecture components are a collection of libraries to ease developing MVVM-based Apps

- Part of Android Jetpack 🚀 They include:

  o ViewModel stores UI-related data that isn't destroyed on screen rotation

  o LiveData data holder that notifies the ViewModel when the model data changes

  o Room to read / write data to local SQLite database

```
▼ ▣ main
  ▼ ▣ java
    ▼ ▣ com.example.test.mvvmsampleapp
      ▼ ▣ model
          C ⌐ Project
          C ⌐ User
      ▼ ▣ repository
          I ○ GitHubService
          C ⌐ ProjectRepository
      ▼ ▣ view
        ▼ ▣ ui
            C ⌐ MainActivity
            C ⌐ Project
            C ⌐ ProjectList
      ▼ ▣ viewmodel
          C ⌐ ProjectListViewModel
          C ⌐ ProjectViewModel
```

**You may organize the view by feature**

ViewModel

Lifecycle Aware

Survives Config Changes

ViewModel

- [ViewModel](#) is used to **store and manage** state (i.e., data needed by the UI)
  - in a lifecycle conscious way
  - allows **state** to survive device configuration changes such as *screen rotations* or *changing the device's language*

View

ViewModel

Data & Computation

- If the system destroys or re-creates a UI component (e.g., when the screen rotates), any transient UI-related data stored in it is lost
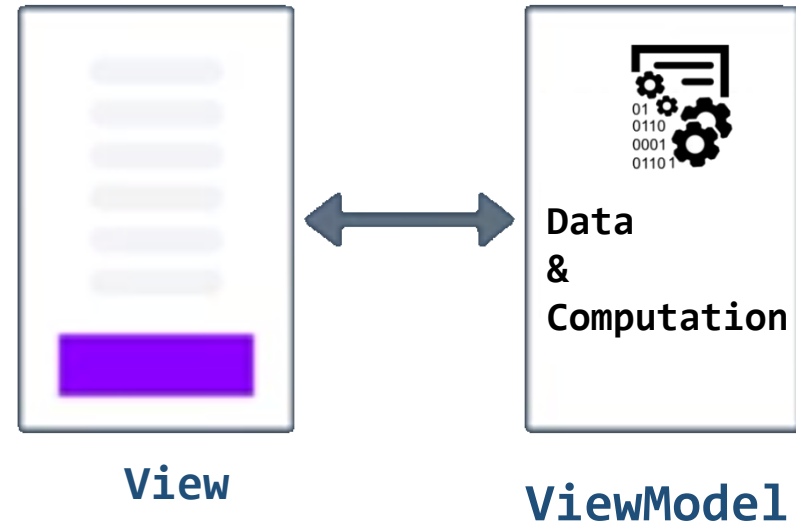

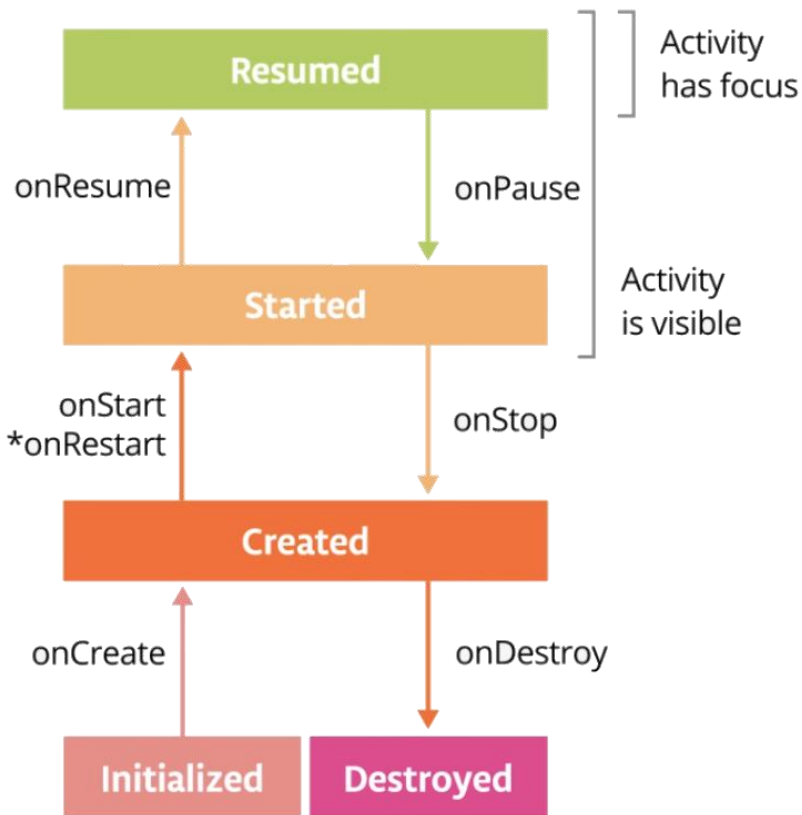

Use **ViewModel**:
- Manages state
- Read/write data from a Repository

Activity Lifecycle

An activity has essentially **four states**:

- ***Resumed*** if the activity in the foreground of the screen (has focus)

- ***Started*** if the activity has lost focus but is still visible (e.g., beneath a dialog box).
  - When the user returns to the activity, it is **resumed**

- **Created** if the activity is completely obscured by another activity.
  - When the user navigates to the activity, it must be **restarted** and restored to its previous state.

- **Destroyed** when the user closes the app or if the activity is killed (when memory is needed or due to `finish()` being called on the activity)

ViewModel Lifecycle

- ViewModel object can be scoped to the main activity

- However, it has a **longer lifespan** compared to the associated Activity which may undergo a rotation and get recreated

- It remains in memory until the activity is completely destroyed
  - When the activity is recreated (after a screen rotation) the associated ViewModel remains alive

Activity created — onCreate
onStart
onResume

Activity rotated

onPause
onStop
With isFinishing = false → onDestroy
onCreate
onStart
onResume

finish()

onPause
With isFinishing = true → onStop
onDestroy

Finished

ViewModel Scope

onCleared()

ViewModel Example

```kotlin
class ScoreViewModel : ViewModel() {

    var team1Score = mutableStateOf(0)

    fun onIncrementTeam1Score() { team1Score.value++ }

}

@Composable
fun ScoreScreen() {
    // Get an instance of the ScoreViewModel

    val scoreViewModel = viewModel<ScoreViewModel>()
    Text(text = scoreViewModel.team1Score.value)
    Button(onClick = { scoreViewModel.onIncrementTeam1Score() }) {
        Text(text = "+1")
    }
    ...
}
```

Add this dependency to build.gradle:
implementation "androidx.lifecycle:lifecycle-viewmodel-compose:2.4.0-beta01"

Using ViewModel with Compose Navigation

- By default, Jetpack Compose Navigation associate the viewModel to each destination

  o The viewModel get destroyed when navigation to another destination

- To create a **shared** viewModel make the viewModel **scoped** to the activity (by assigning the activity as the viewModel Store Owner)
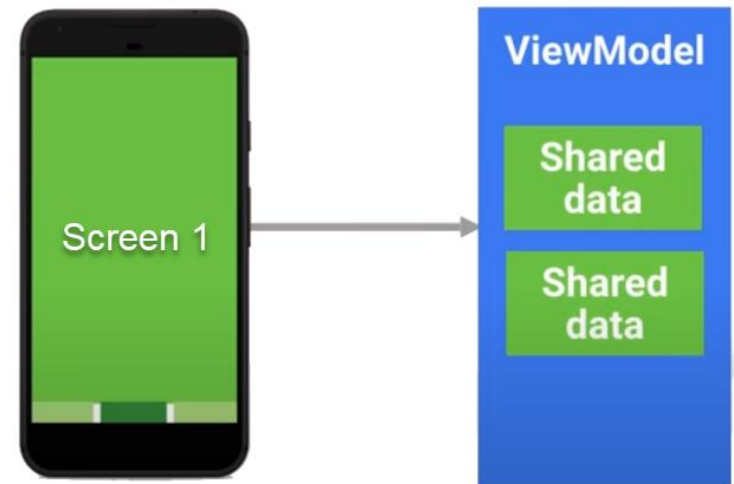

```
/* To allow any screen to get an instance of the shared viewModel
   make the viewModel scoped to the activity (by assigning the activity as
   the viewModel Store Owner)
   This ensures that the same viewModel instance is used for all screens
*/

val scoreViewModel = viewModel<ScoreViewModel>
        (viewModelStoreOwner = LocalContext.current as ComponentActivity)
val team1Score = scoreViewModel.team1Score
```

Shared data between Screens using ViewModel

Will be discussed Later

- Screens can **share** data using a shared **View Model** class that extends `ViewModel()`

```kotlin
@Composable
fun ProfileScreen(userId: Int) {
 /* Get an instance of the shared viewModel
   Make the activity the store owner of the viewModel
   to ensure that the same viewModel instance is used for all screens */
 val userViewModel = viewModel<UserViewModel>(viewModelStoreOwner =
 LocalContext.current as ComponentActivity)
 val user = userViewModel.getUser(userId)
... }
```

ViewModel scoped to the Activity

- Use **viewModel()** method to get an instance of the ViewModel

```
val scoreViewModel = viewModel<ScoreViewModel>
        (viewModelStoreOwner = LocalContext.current as ComponentActivity)
```

- o For the first call, this creates and returns a new ViewModel instance **scoped** to the activity (i.e., associated with the Main Activity) to make it **shared** and accessible from all screens

- o For subsequent calls, `viewModel()` method will return the pre-existing ViewModel scoped to the Activity
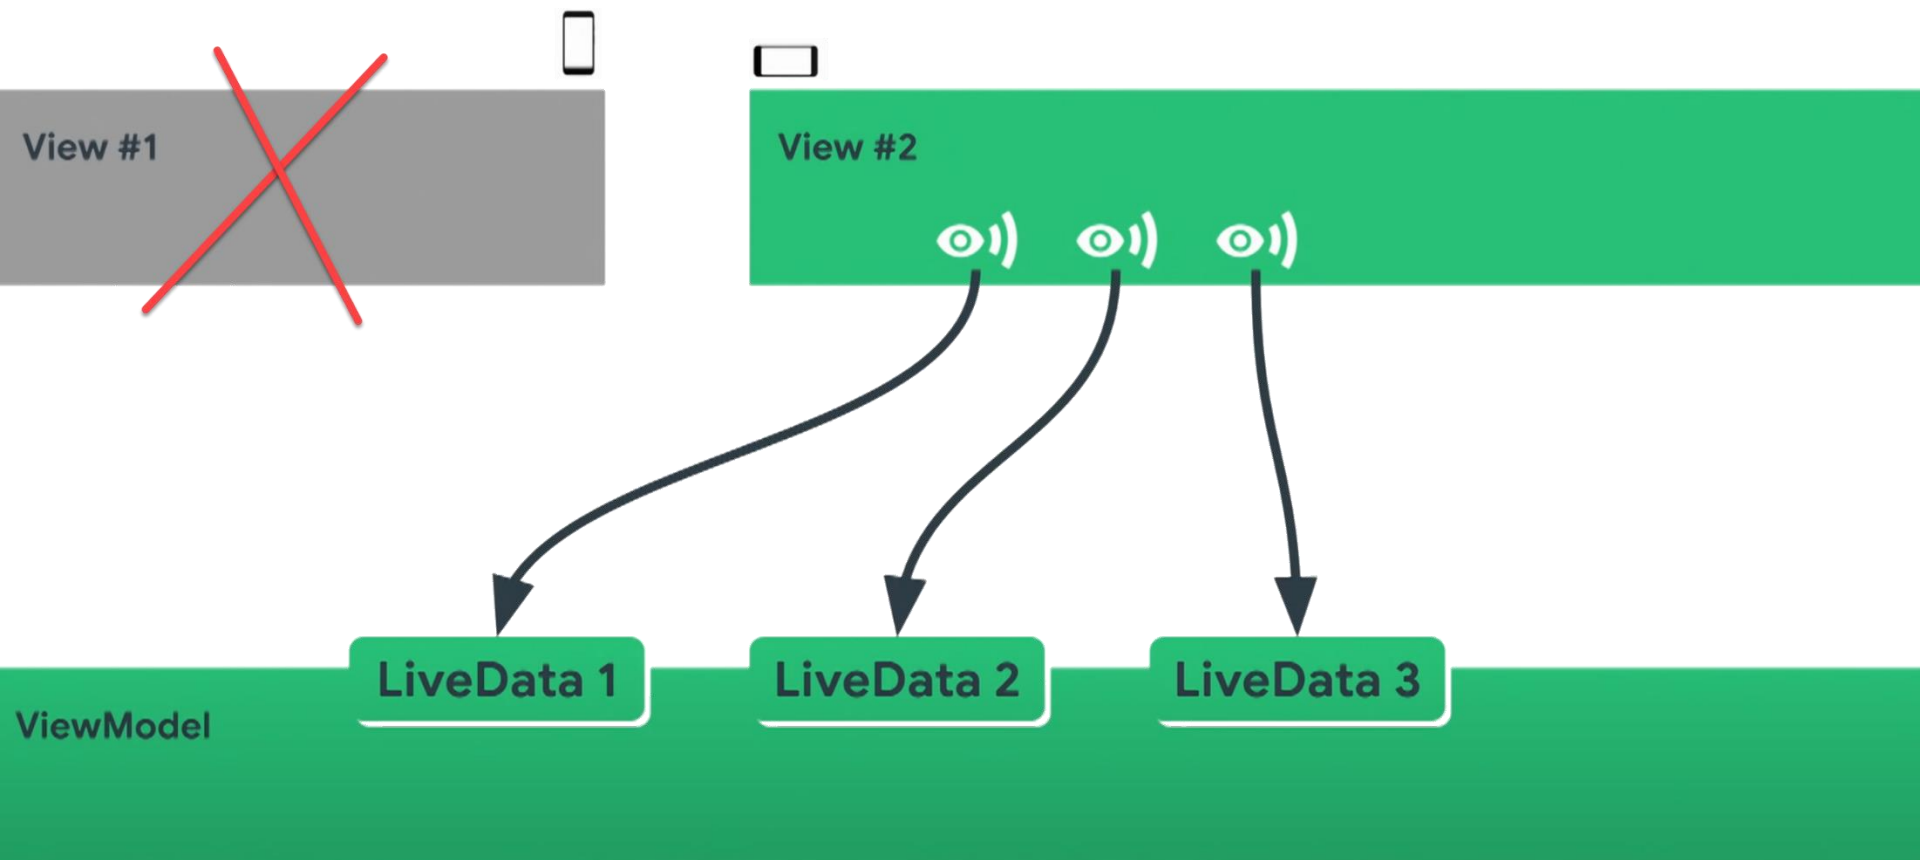

When the ViewModel is first Created

When the ViewModel is first created, the **new ViewModel instance** get associated with the Activity
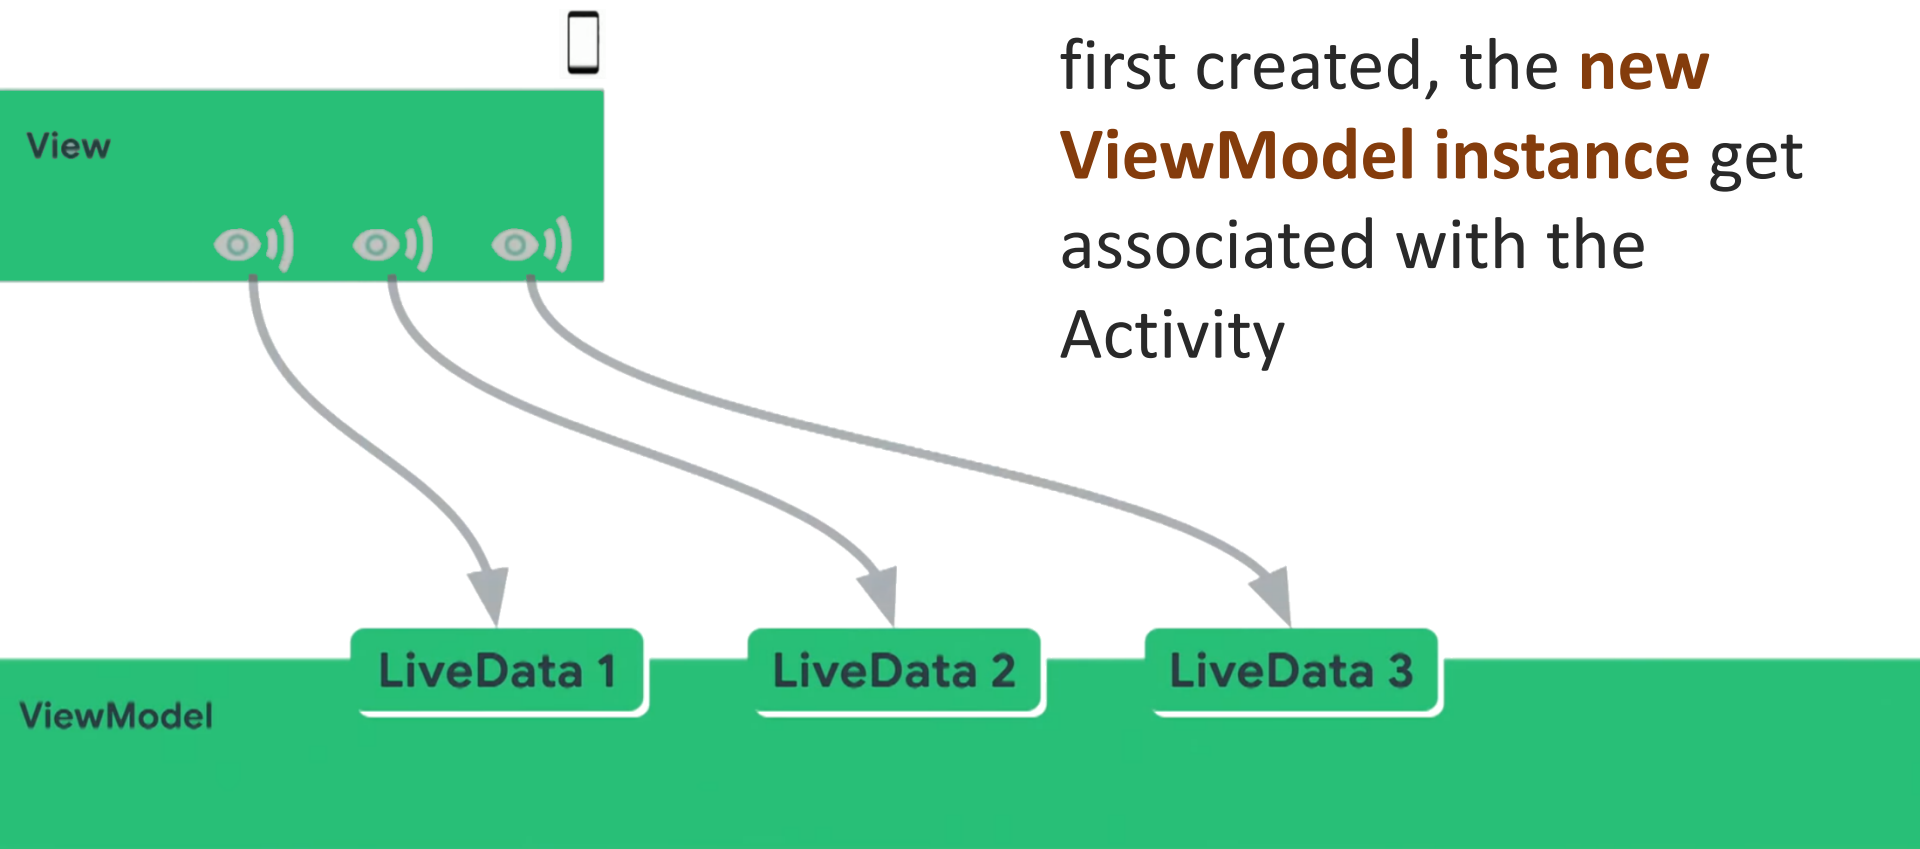

OnConfig change (e.g., Screen Rotates)

OnConfig change, the View is destroyed, and a new instance of the View is created then it obtains **the same ViewModel instance used previously**

"no contexts in ViewModels" rule

- ViewModel should **not be aware of the View** who is interacting with
  => It should be <mark>decoupled</mark> from the View

  o ViewModel <u>should not hold a reference to Activities</u> or Views (i.e. Composables)

  o Should not have any Android framework related code

  o As this defeats the purpose of separating the UI from the data

  o Can lead to memory leaks and crashes (due to null pointer exceptions) as the ViewModel <u>outlives</u> the View

    - if you rotate an Activity 3 times, 3 three different Activity instances will be created, but you only have one ViewModel instance

Mutable State

Mutable State

- Mutable State is an **observable data holder**: **active** observers (i.e., the View) get notified when data change

  o Mutable State warps around an object and allows the view to observe it

- The View can observe Mutable State variables for changes without creating **explicit and rigid dependency** between the View and the ViewModel

  o The ViewModel exposes its data using **Mutable State** that the View observes and update the UI accordingly

  o This decouples ViewModel from the View (i.e., the ViewModel does not have any reference to the View)

Mutable State Example

```kotlin
class ScoreViewModel : ViewModel() {

    var team1Score = mutableStateOf(0)

    fun onIncrementTeam1Score() { team1Score.value++ }
}

@Composable
fun ScoreScreen() {
    // Get an instance of the ScoreViewModel

    val scoreViewModel = viewModel<ScoreViewModel>()
    Text(text = scoreViewModel.team1Score.value)
    Button(onClick = { scoreViewModel.onIncrementTeam1Score() }) {
        Text(text = "+1")
    }
    ...
}
```
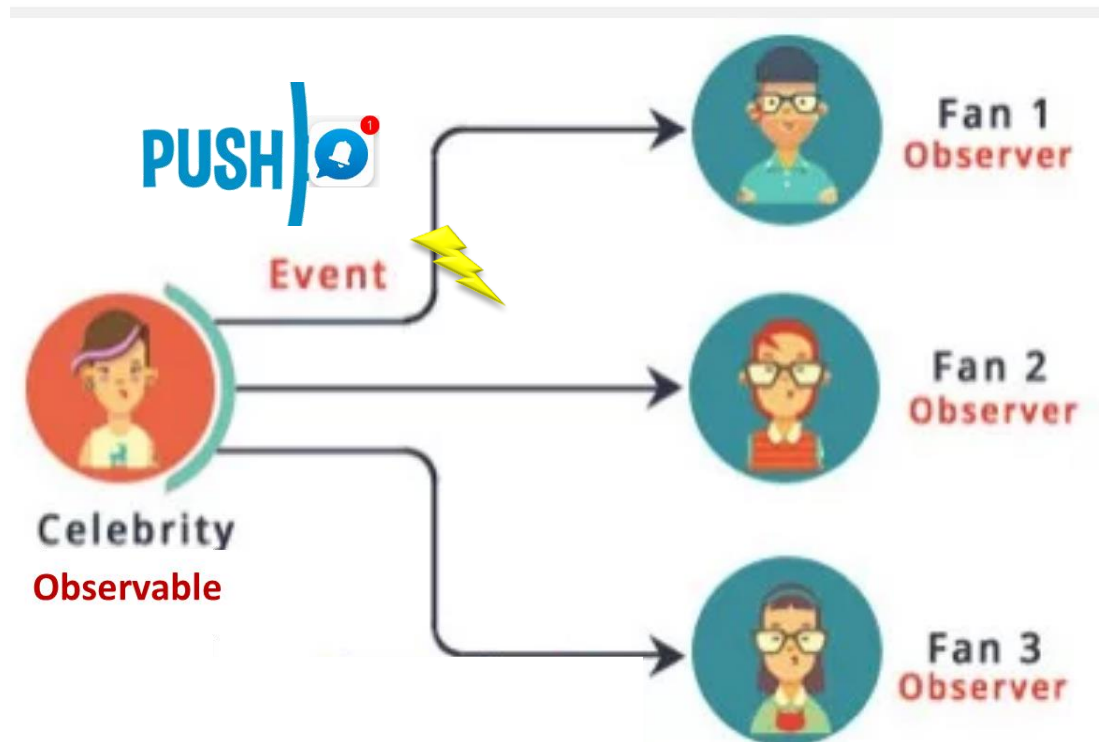

LiveData

LiveData

- LiveData is an **observable data holder**: **active** observers (i.e., the ViewModel) get notified when data change

- The ViewModel can observe LiveData objects for changes without creating **explicit and rigid dependency** between the ViewModel and the Repository

  - The Repository exposes its data using **LiveData** that the ViewModel can observe and notify the UI accordingly

  - This decouples the Repository from the ViewModel: The Repository does not have any reference to the ViewModel

Observable - Real-Life Example

- A celebrity who has many fans on Instagram. Fans want to get all the latest updates (photos, videos, posts etc.). Here fans are **Observers** and celebrity is an **Observable** (called **LiveData** on Android)

LiveData is lifecycle-aware

LiveData is aware of the Lifecycle of its Observer

- Notifies data changes to only **active** observers (Stopped/Destroyed View will NOT receive updates)

- It automatically removes the subscription when the observer is destroyed so it will not get any updates

LiveData in Code

LiveData **warps around** an object and allows the view to **observe** it
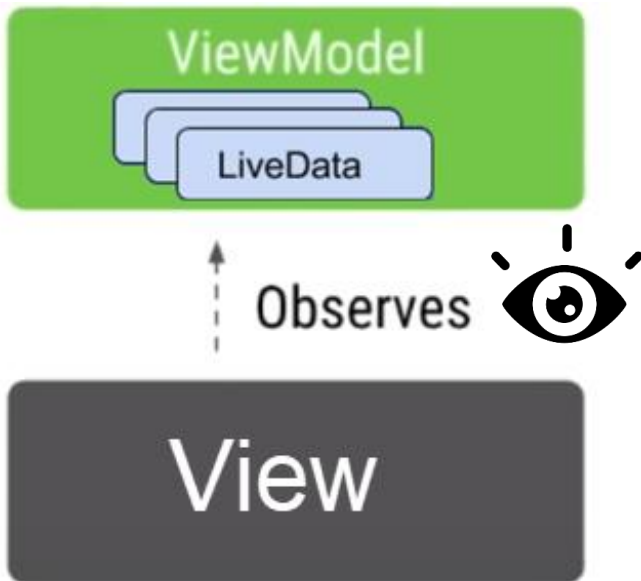

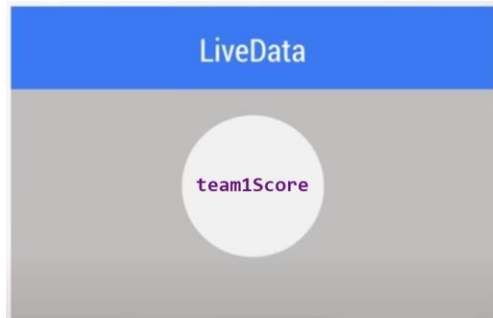

- ViewModel expose LiveData objects that the View can observe

```kotlin
object DataRepository {
    // In a real app the LiveData will be returned by
    // a database or Web API as we will see later
    fun getRedCardsCount(): LiveData<Int> = LiveData {
        emit(2)
    }
}
```

```kotlin
class ScoreViewModel : ViewModel() {
    val redCardsCount = DataRepository.getRedCardsCount()
}
```

- View **observes** LiveData changes

```kotlin
@Composable
fun ScoreScreen() {
    val scoreViewModel = viewModel<ScoreViewModel>()
    val redCardsCount = scoreViewModel.redCardsCount
                                      .observeAsState(0)
// Recomposes whenever redCardsCount changes
Text(
  text = "Red cards count: ${redCardsCount.value}")
} ... }
```

LiveData.observeAsState()

- LiveData.**observeAsState()** registers as a **listener** and represent the values as a State

  o Whenever a new value is emitted, Compose recomposes those parts of the UI where that state.value is used

  o Required dependency in `build.gradle`:

```
implementation "androidx.compose.runtime:runtime-livedata:$compose_version"
```

Flow

# What is Flow?

🌊 Stream of values (produced one at a time instead of all at once)

   🌊 Values could be generated from network requests or database calls

🌊 Can transform a flow using operators like map, filter, etc.

```kotlin
fun stream(): Flow<String> = flow {
    emit("🌊") // Emits the value upstream ☝
     emit("⚽")
    emit("🥕")
}
```

```kotlin
object WeatherRepository {
    private val weatherConditions = listOf("Sunny", "Windy", "Rainy", "Snowy")
    fun getWeather(): Flow<String> =
        flow {
            var counter = 0
            while (true) {
                counter++
                delay(2800)
                emit(weatherConditions[counter % weatherConditions.size])
            }
        }
}
```

```kotlin
class WeatherViewModel : ViewModel() {
    val weatherFlow: Flow<String> = WeatherRepository.getWeather()
}
```

```kotlin
@Composable
fun ScoreScreen() {
    val weatherViewModel = viewModel<WeatherViewModel>()

    val weatherFlow = weatherViewModel.weatherFlow.collectAsState(initial = "")
    // Recomposes whenever redCardsCount changes
    Text(
      text = "Red cards count: ${weatherFlow.value}" )
    } ... }
```

Flow Operators

- Flow has operators similar to collections such as map, filter and reduce

```
(1..5).asFlow()
    .filter { it % 2 == 0 }
    .map { it * it }
    .collect { println(it.toString()) }

val result =(1..5).asFlow()
                    .reduce { a, b -> a + b }
println("result: $result")
```
